Bioinformatics analysis and biological experiments support an emerging role of ELK3 in glioma

Type
Research paper

Keywords
prognosis, migration, glioma, epithelial-mesenchymal transition, ELK3

Abstract
Introduction
Glioma is a malignant tumor that recurs easily. This study aimed at investigating the biological effect of ELK3 in epithelial-mesenchymal transition (EMT) and its prognostic value.

Material and methods
Bioinformatics analyses were performed to determine the expression and prognostic value of ELK3. The biological properties of glioma cells (A172 and LN229) were evaluated by cell counting kit-8, plate cloning and transwell assays. Gene Expression Profiling Interactive Analysis (GEPIA) website was used to analyze the relationship between ELK3 expression and EMT-related markers. Western blotting was applied to detect the protein levels.

Results
ELK3 is highly expressed in glioma and significantly associated with poor prognosis (p < 0.05), presenting promising value in the diagnosis and prognostic prediction of glioma. Further biological assays revealed that cell viability was notably reduced after down-regulating ELK3 (p < 0.01). The numbers of colonies formed by A172 (145.30 ± 12.86 vs. 300.30 ± 11.68) and LN229 (125.70 ± 4.04 vs. 256.00 ± 20.07) cells were decreased after transfection of si-ELK3 (p < 0.01). The numbers of invaded and migrated glioma cells in si-ELK3 group were decreased by about half (p < 0.01). Moreover, ELK3 was positively correlated with N-Cadherin (R = 0.21), Snail1 (R = 0.43), Slug (R = 0.6) and Vimentin (R = 0.35), and depletion of ELK3 reduced the levels of these EMT-related markers more than a half (p < 0.01).

Conclusions
Our observations illustrated that ELK3 was highly expressed in glioma and played a promoting role in the growth and mobility of glioma cells partly by modulating EMT progress.
Bioinformatics analysis and biological experiments support an emerging role of ELK3 in glioma

The running title: ELK3 acted as an oncogene in glioma

1. Introduction

Gliomas are the common highly malignant primary tumors of the brain and spinal cord, with a median survival time of less than 16 months after diagnosis [1]. Histologically, they have the properties of normal glial cells and are usually named based on these similarities [2]. Despite the continuous improvement of surgical resection, radiotherapy, chemotherapy and other treatment methods, the survival rate of glioma patients is still low [3, 4]. This is mainly due to its highly aggressive growth pattern, prominent tumor angiogenesis, and high resistance to treatment [5]. As the prognosis of glioma patients is dismal and the therapeutic effect is poor, it is particularly urgent to explore new markers for early diagnosis and treatment of glioma. At the same time, elucidating the molecular mechanism of glioma may also provide a new direction for the treatment of glioma.

The biological functions of E-twenty-six (ETS) transcription factor ELK3 (ELK3) in tumors have been preliminarily validated by several researchers. For example, ELK3 has been found to be expressed in lymphatic endothelial cells and promote the development and metastasis of breast cancer [6]. Furthermore, ELK3 can contribute to the invasion and migration of liver cancer stem cells by regulating HIF-1α [7]. Besides, it has been reported that mice lacking ELK3 protein developed smaller tumors, which were not able to become vascularized and oxygenated, suggesting that ELK3 held a primary role in tumorigenicity [8]. Hence, the existing literatures revealed that ELK3 played an important role in the growth and mobility of tumor cells. However, report on the function and mechanism of ELK3 in glioma is still rare.

Epithelial-mesenchymal transition (EMT) is a multistep and dynamic process during which epithelial cells’ phenotypic features are lost [9]. It plays an important role in generating and maintaining the malignant characteristics of primary glioma as well as grades II-III glioma [10]. Certain transcription factors such as Slug and Snail have been reported to be involved in EMT, and promote the migration and invasion of glioma cells [11]. Vimentin and N-cadherin are critical mesenchymal biomarkers of EMT process [12]. It has been reported that ELK3 contributes to the process of liver fibrosis via modulating EMT [9]. In addition, ELK3 is identified as a partner of ZEB1
to suppress the expression of E-cadherin in Triple-Negative Breast Cancer Cells [13]. Whether ELK3 involved in EMT process in glioma remains unknown.

In this study, the intention has been to investigate the expression and the prognostic value of ELK3 using the data of glioma from the public available database. Moreover, the malignant behaviors of glioma cells and the expression of EMT-related proteins were examined after depletion of ELK3 to reveal the biological functions of ELK3 in glioma.

2. Materials and methods

2.1 Bioinformatics analyses

Data of 168 tumor samples and 110 normal samples that downloaded from The Cancer Genome Atlas (TCGA) database and Genotype-Tissue Expression (GTEx) database, was used to analyze the differential expression of ELK3. Receiver operating characteristic (ROC) curve analysis was performed for assessing whether ELK3 was capable of discriminating glioma and normal samples. mRNAseq_325, mRNAseq_693 and mRNA_array_301 datasets were downloaded from Chinese Glioma Genome Atlas (CGGA) database and applied to detect the expression of ELK3 and its prognostic value in patients with different World Health Organization (WHO) tumour stages, patients ages and recurrence status. Gene Expression Profiling Interactive Analysis (GEPIA) website was applied to analyze the association between ELK3 expression and N-Cadherin, Snail1, Slug or Vimentin.

2.2 Cell culture and transfection

Shanghai Cell Bank of the Chinese Academy of Sciences (Shanghai, China) provided the glioma cell lines A172 and LN229. A172 cell line was originally from the brain of a 53 year old male with glioblastoma. It was not tumorigenic in immunosuppressed mice. The LN229 cell line was originally from a patient with right frontal parieto-occipital glioblastoma. This cell line displayed mutated p53 and possible homozygous deletions in the p16 and p14ARF tumor suppressor genes, and possessed a wild-type PTEN gene. These two cell lines are commonly used strains for studying glioma in vitro. The normal human astrocyte (NHA) cell line was obtained from Sciencell Research Laboratories and used as control. All cell lines were cultured
in Dulbecco Modified Eagle medium (DMEM) with antibiotics at 37 °C with 5% CO₂. Si-ELK3#1 and si-ELK3#2 were siRNAs that applied to down-regulate ELK3 expression, and si-con served as a corresponding control. All these oligonucleotides were synthesized by Sangon (Shanghai, China) and transfected into A172 and LN229 cells by Lipofectamine 2000 (Invitrogen, USA). The sequences of these siRNAs were listed below:

si-ELK3#1: 5’-GCCACAATTAAGGACTCATTA-3’;
si-ELK3#2: 5’-TGGATCAGAAACATGAGCATT-3’;
si-con: 5’-AATTCTCCGAACGTGTCACGT-3’.

2.3 Quantitative Real-Time Polymerase Chain Reaction (qRT-PCR)

Total RNA from A172 and LN229 cells was extracted by using TRIzol reagent (TaKaRa, China) based on the supplier’s instruction. To quantify the expression of ELK3, we firstly synthesized cDNA from total RNA using the PrimeScript RT Reagent kit (TaKaRa, China). Then, qRT-PCR was performed utilizing SYBR Green Mix in a 7900 HT RT-PCR machine and GAPDH was used as an internal control for normalization. The relative expression of ELK3 was processed by \(2^{-\Delta\Delta C_T}\) method. The sequences of the primers were listed below:

ELK3 forward: 5’-TTCTGACTCCGAGTCCACTGCT-3’,
   reverse: 5’-AGCTCTGTCCAGACTGGGGATT-3’;
GAPDH forward: 5’-GTCTCCTCTGACTTCAACAGCG-3’,
   reverse: 5’-ACCACCCCTGTGTGCTGAGCCAA-3’.

2.4 Western blotting

A172 and LN229 cells were lysed, and the protein extracts were denatured. The proteins (25 µg) were subjected to sodium dodecyl sulfate polyacrylamide gel electrophoresis, blotted onto polyvinylidene fluoride membranes and probed with specific primary antibodies against ELK3, N-cadherin, Snail, Slug, Vimentin and GAPDH. Afterwards, the membranes were incubated with the secondary antibody and the signals of the objective proteins were visualized by enhanced chemiluminescence. Finally, the intensity of the bands was evaluated by Image J software.

2.5 Cell counting kit-8 (CCK-8) assay
For CCK-8 assay, the treated A172 and LN229 cells were implanted into a 96-well plate (1000 cells/well). The cells were routinely cultured in a carbon dioxide incubator at 37 °C, and the cell viability was monitored every 24 h. Before each test, the CCK-8 solution (10 μL) was loaded into each well based on the supplier’s instruction. Then the plate was kept in the incubator at 37 °C for 1.5 h. After 1.5 h incubation, the optical density was examined at 450 nm wavelength.

2.6 Plate colony formation assay

For testing the ability of the cells to form colonies, a total of 500 A172 and LN229 cells were seeded in a 60 mm petri dish and grew in the medium containing 10% fetal bovine serum (FBS). After 10-14 days of incubation, the emerging colonies were fixed, stained and manually counted. Each experiment was repeated at least three times.

2.7 Cell invasion and migration assays

For cell invasion assay, a 24-well transwell chamber (Corning, New York, USA), coated with Matrigel (BD Bioscience, USA) was used. Briefly, 100 μL serum free medium was added to the upper chamber and incubated at 37 °C for 1 h. A172 and LN229 cells were implanted into the upper chamber at a concentration of 5×10^3 cells/well, and 500 μL complete medium containing 10% FBS was put into the lower chamber. After cultivation for 24 h at 37 °C, the invaded cells were fixed and stained. Five fields were randomly selected to take photos. The steps of migration assay were similar to the invasion assay except that the wells in upper chamber did not require Matrigel.

2.7 Statistical analyses

SPSS22.0 and Graphpad Prism 8.0 software were used to process the experimental data, which was expressed as mean ± standard deviation (SD). Student’s t test or analysis of variance (ANOVA) was applied to analyze the difference among groups. Kaplan-Meier analysis was applied to analyze the overall survival of glioma patients with different ELK3 expression and log-rank test was used for comparison. The expression of ELK3 in patients with glioma was categorized as low expression or high expression according to the median value. P value less than 0.05 was considered
to indicate a statistically significant difference.

3. Results

3.1 The expression, prognostic value and clinical significance of ELK3 in glioma

Expression data analyses of 168 tumor samples from TCGA and 110 normal samples from TCGA and GTEx illustrated that the expression of ELK3 was significantly higher in glioma samples than that in normal samples (fig. 1A). Moreover, the result from ROC analysis displayed that the area under the curve (AUC) was 0.9995 (p < 0.001), indicating that ELK3 expression was of great diagnostic value in distinguishing glioma from normal samples (fig. 1B). Besides, the survival analysis showed that the overall survival of glioma patients in the high ELK3 expression group was shorter than that of the low ELK3 expression group (fig. 1C).

Next, the expression of ELK3 in patients with different WHO tumour stages, ages, recurrence status was analyzed based on the mRNAseq_325, mRNAseq_693 and mRNA_array_301 datasets from CGGA database. mRNAseq_325 and mRNAseq_693 are RNA-seq datasets, while mRNA_array_301 is a micro array dataset. The sample numbers of these 3 datasets were presented in table 1. The results displayed that the expression of ELK3 in WHO IV tumour grade was higher than that in WHO II and WHO III tumour grades and the difference was statistically significant (fig. 2A-C, p < 0.001). Additionally, the data from mRNAseq_325 dataset showed that ELK3 expression was higher in the glioma patients over 42 years old (fig. 2D, p < 0.001). Similarly, the data from mRNA_array_301 dataset displayed that ELK3 expression was higher in the glioma patients older than 43 years old compared with patients younger than 43 years (fig. 2E, p = 0.029), which indicating that ELK3 tended to present a higher level in older people. Moreover, the data from mRNAseq_693 dataset illustrated that ELK3 expression was higher in patients with recurrent glioma than that with primary glioma (fig. 2F, p = 0.003). The prognostic analysis revealed that high expression of ELK3 led to poor survival rate in the WHO II and WHO III tumour grades (fig. 2G-I). In addition, high expression of ELK3 resulted in a poor prognosis in patients with primary or recurrent glioma, which was statistically significant (fig. 2J-Q, p < 0.05). All these results suggested that ELK3 is
closely related to the progression of glioma and is a potential biomarker for diagnosis and prognostic prediction.

3.2 Effect of ELK3 on the growth, invasion and migration of glioma cells

Afterwards, we detected the expression of ELK3 in glioma cell lines and the effect of ELK3 expression on the growth and mobility of glioma cells. The data in fig. 3A showed that the levels of ELK3 in A172 and LN229 cells were 2.24 and 2.28 folds of NHA cells, respectively, indicating a significant high expression of ELK3 in glioma cells than normal cells (p < 0.01). After transfection of siRNAs specific to ELK3, ELK3 expression was notably reduced in A172 and LN229 cells (p < 0.01). Si-ELK3#2, with higher interference efficiency, was selected for further study (fig. 3B-D). With si-ELK3 treatment, the OD values of A172 and LN229 cells were significantly lower than the si-con group at 48 h (p < 0.05) and 72 h (p < 0.01), indicating that depletion of ELK3 reduced the viability of A172 and LN229 cells (fig. 4A-B). Data from fig. 4C-E displayed that knockdown of ELK3 remarkably reduced the number of colonies formed by A172 cells (145.30 ± 12.86 vs. 300.30 ± 11.68, p < 0.01) and LN229 cells (125.70 ± 4.04 vs. 256.00 ± 20.07, p < 0.01) compared with the si-con group. Additionally, the invaded and migrated numbers of A172 cells (103.70 ± 5.13 vs. 202.70 ± 11.02; 148.30 ± 3.26 vs. 309.00 ± 7.81; p < 0.01) and LN229 cells (104.30 ± 3.21 vs. 193.00 ± 1.73; 142.00 ± 3.61 vs. 294.30 ± 18.77; p < 0.01) were notably reduced when ELK3 was knocked down (fig. 4F-I). All these findings insinuated that depletion of ELK3 suppressed the malignant properties of glioma cells, further indicating the importance of ELK3 in glioma progression.

3.3 Effect of ELK3 on the expression of EMT-associated proteins in glioma

Through searching GEPIA website, we discovered that ELK3 expression was positively associated with N-Cadherin (R = 0.21, p < 0.01), Snail1 (R = 0.43, p < 0.01), Slug (R = 0.6, p < 0.01) and Vimentin (R = 0.35, p < 0.01) (fig. 5A-D). The results of Western blotting showed that knockdown of ELK3 notably suppressed the expression of N-cadherin, Snail, Slug and Vimentin in A172 and LN229 cells (fig. 5E-H, p < 0.01), indicating that ELK3 possibly executed its function in glioma cells partly through regulating EMT progress.
4. Discussion

Most glioma patients tend to present recurrence and poor prognosis. Despite the treatment regimens have improved, the survival rates for glioma patients have barely changed [14]. Identifying reliable biomarkers with diagnostic and prognostic value and developing effective therapeutics are of great significance. In the present study, the results demonstrated for the first time that ELK3 was highly expressed in glioma samples and its high expression was connected with the poor prognosis of glioma patients. Besides that, knockdown of ELK3 suppressed the malignant properties of glioma cells and the progression of EMT process. These findings suggested that ELK3 might be a novel diagnostic and prognostic maker as well as a therapeutic target for glioma.

ELK3, also named as Net, SAP-2, or Erp, is a protein containing the ETS domain that forms a ternary complex with DNA and serum response factor (SRF) [7], distinguished from other members of the ETS family by its ability to inhibit transcription [8]. ELK3 has been reported to contribute to the development and metastasis of breast cancer [6, 15] and facilitate the invasion and migration of liver cancer stem cells [7]. In addition, high ELK3 expression is revealed to be associated with the gastric tumorigenesis and could enhance the infiltration of M2 macrophages [16]. All these data supported the critical role of ELK3 in the progression of several tumors. Herein, ELK3 was found to be up-regulated in glioma tissues and its high expression is correlated with poor prognosis. Age is a critical factor of cancer risk. The age of patients with gliomas is an independent prognostic factor for overall survival [18]. Of note, the results in this study found that the expression of ELK3 was higher in older patients, suggesting the relation of the ELK3 expression and the age of patients with gliomas. Moreover, the biological experiments in the present study illustrated that depletion of ELK3 suppressed the proliferation and mobility of glioma cells. These findings consistently suggested the promoting role of ELK3 during glioma progression.

A better understanding of the molecular mechanism of glioma growth and motility is necessary to enhance the efficacy of clinical therapy in inhibiting glioma
metastasis. EMT induces cells to lose their epithelial properties, achieve invasive and migratory capacity and change from epithelial cell community to mesenchymal cells [17, 18]. As a key factor of tumor invasion enhancement, EMT has been illustrated to be implicated in the malignant development of glioma [19, 20]. Moreover, we know that tumor cells and stromal components cooperatively participate in the malignant development and recurrence of glioma [19]. Just because of this, the study of EMT in glioma is crucial to reverse malignant development and reduce recurrence. It has been reported that ELK3 plays a central role in the EMT process, leading to liver fibrosis through MAPK pathway [21]. Previously, a study revealed that inhibition of ELK3 impaired the ability of TGFβ signaling to activate the expression of mesenchymal markers such as Snail, Vimentin, and Slug in the breast cancer cells [22, 23]. Analysis from GEPIA website displayed that ELK3 expression was positively related with N-cadherin, Snail, Slug and Vimentin. Moreover, the biological experiments further identified the associations between ELK3 and EMT-related markers, which showed that knockdown of ELK3 suppressed the expression of N-cadherin, Snail, Slug and Vimentin in glioma cells. These observations indicated that ELK3 promoted the progression of glioma at least partially by activating EMT process.

In conclusion, ELK3, which is highly expressed in glioma, is predictive of a poor prognosis for patients with glioma. Furthermore, ELK3 contributed to the growth and mobility of glioma cells partly through regulation of EMT process, indicating that inhibition of ELK3 expression might be a valuable therapeutic strategy for preventing the progress of tumor growth and metastasis.

Disclosure of interest
The authors report no conflict of interest.

Data availability statement
The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

Figure legends

**Figure 1.** ELK3 was differentially expressed in tumors and had great values in glioma diagnosis. A. ELK3 expression was notably increased in glioma samples than the corresponding control, p < 0.0001. B. Receiver operating characteristic (ROC) curve indicated that ELK3 had high diagnostic value, p < 0.0001. C. Glioma patients in ELK3 high expression group presented a shorter overall survival than that in ELK3 low expression group, p = 0.006.

**Figure 2.** Expression of ELK3 in glioma patients with different WHO tumour grades, patients ages and recurrent states. A-C. Data from mRNAseq_325.
mRNAseq_693 and mRNA_array_301 datasets indicated that ELK3 expression was higher in WHO IV tumour grade than that in WHO II and WHO III tumour grades. D-E. ELK3 expression was higher in older glioma patients. F. Compared with primary glioma, ELK3 expression was increased in recurrent glioma. G-Q. In different WHO tumour grades of glioma and recurrent glioma, high expression of ELK3 led to a poor survival rate. The numbers in parentheses represented the sample size.

**Figure 3. ELK3 expression was increased in glioma cells and reduced with si-ELK3 treatment.** A. The expression of ELK3 was increased in A172 and LN229 cells compared with the NHA cells, **p < 0.01.** B-D. The mRNA and protein expression levels of ELK3 were notably reduced in A172 and LN229 cells when treated by si-ELK3#1 or si-ELK3#2, **p < 0.01 vs. si-con.

**Figure 4. The malignant behaviors of glioma cells were suppressed by si-ELK3 treatment.** A-B. The OD values of A172 or LN229 cells were notably reduced when ELK3 was knocked down. C-E. The numbers of colonies formed by A172 and LN229 cells were declined significantly by si-ELK3 treatment. F-I. The invaded and migrated numbers of A172 or LN229 cells were reduced obviously after si-ELK3 treatment. *p < 0.05, **p < 0.01 vs. si-con.

**Figure 5. EMT-related genes were regulated by ELK3 in glioma.** Analysis from GEPIA indicated that ELK3 expression was positively related to N-cadherin (A), Snail1 (B), Slug (C) and Vimentin (D). E-F. In A172 cells, knockdown of ELK3 reduced the protein expression of N-cadherin, Snail, Slug and Vimentin. G-H. Knockdown of ELK3 suppressed the expression of N-cadherin, Snail, Slug and Vimentin in LN229 cells. **p < 0.01 vs. si-con.
